EXPERIMENT 9

Name: Pranav Shanmugam
Roll No: 240701395

AIM:

To create a form that checks whether the entered details like email and phone number are valid and to show error messages using HTML, CSS and JavaScript.

DESCRIPTION:

In this experiment, we learn how validation works on the client side. Instead of allowing wrong data to be submitted, the form checks the inputs before submission. This helps in avoiding mistakes and improves the overall user experience.

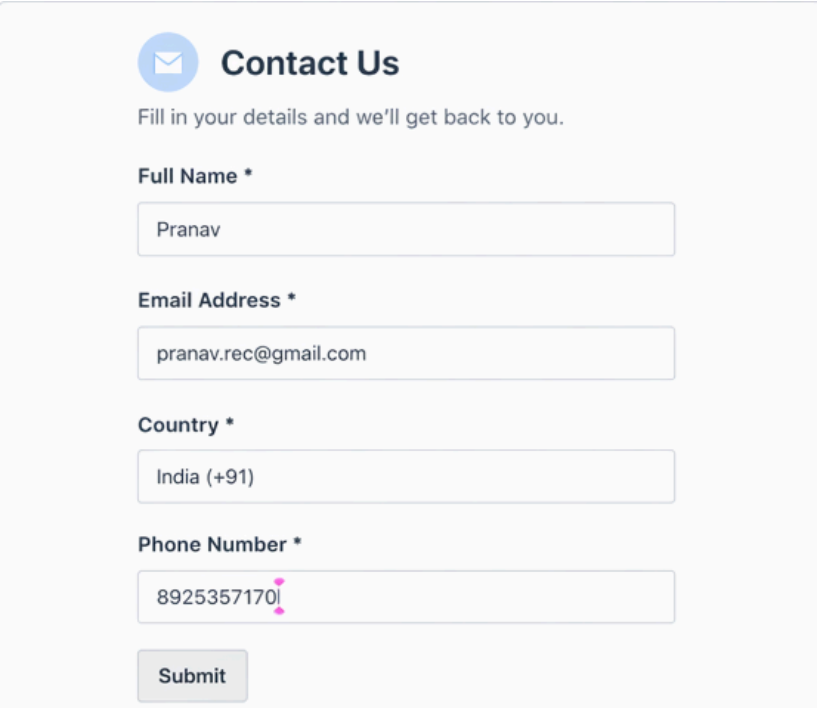
STEP 1: Creating the HTML Form

First, an HTML form is created with input fields for email and phone number.

A form element is used to hold all the input fields together. Inside the form, input tags are used to create fields such as:

- One field for name and email, where the user enters basic details
- One field for phone number to enter contact information

Each field is properly labeled so that it is easy for the user to understand what to enter. A submit button is also added at the end to send the data.



STEP 2: Styling the Form using CSS

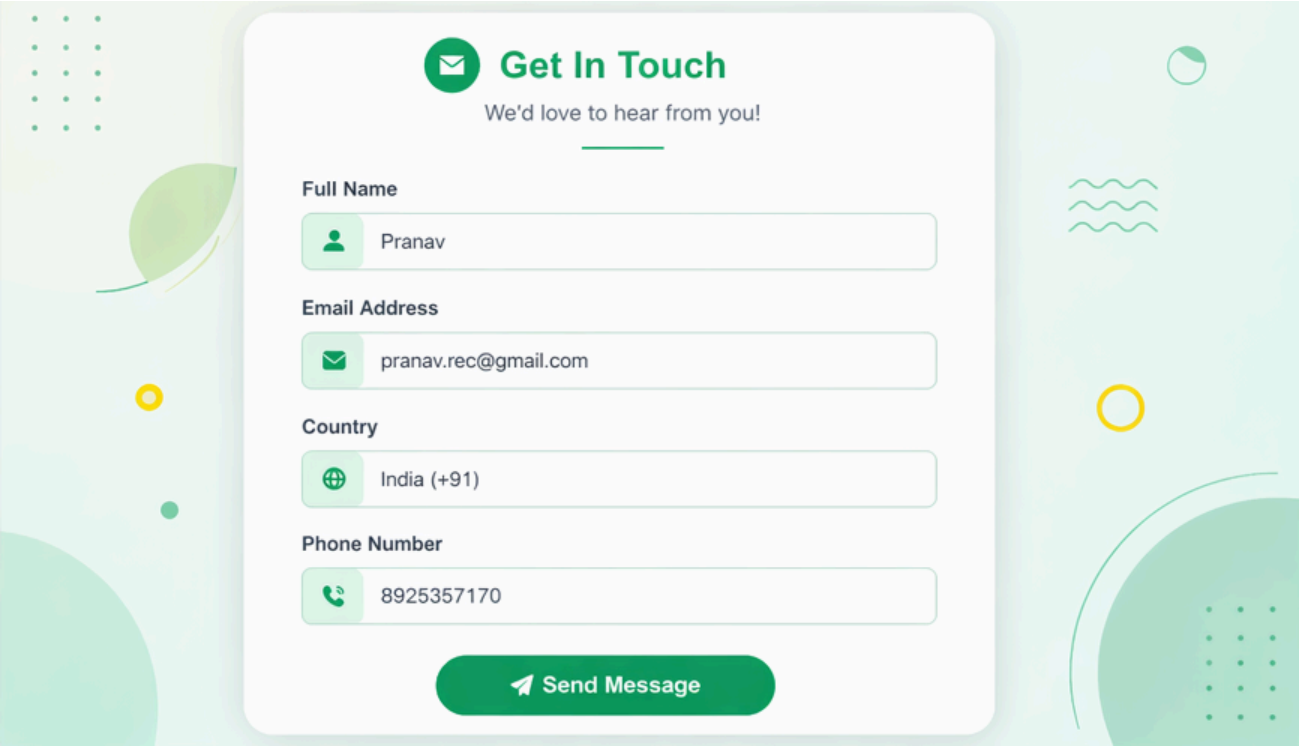
Next, CSS is applied to make the form look better.

In this step, styling is used to improve how the form appears on the screen. It helps in arranging the layout properly and makes the form easier to read and use.

The input fields are given proper spacing, width and padding so that typing becomes easier. The submit button is also styled using colors and hover effects so that it looks more interactive.

Some additional design features included are:

- Gradient background for a better visual look
- Card style layout with slight blur effect
- Improved input field design
- Simple animations and transitions
- Better font and spacing
- Button click effects
- Small shake effect when error occurs



STEP 3: Adding JavaScript Validation

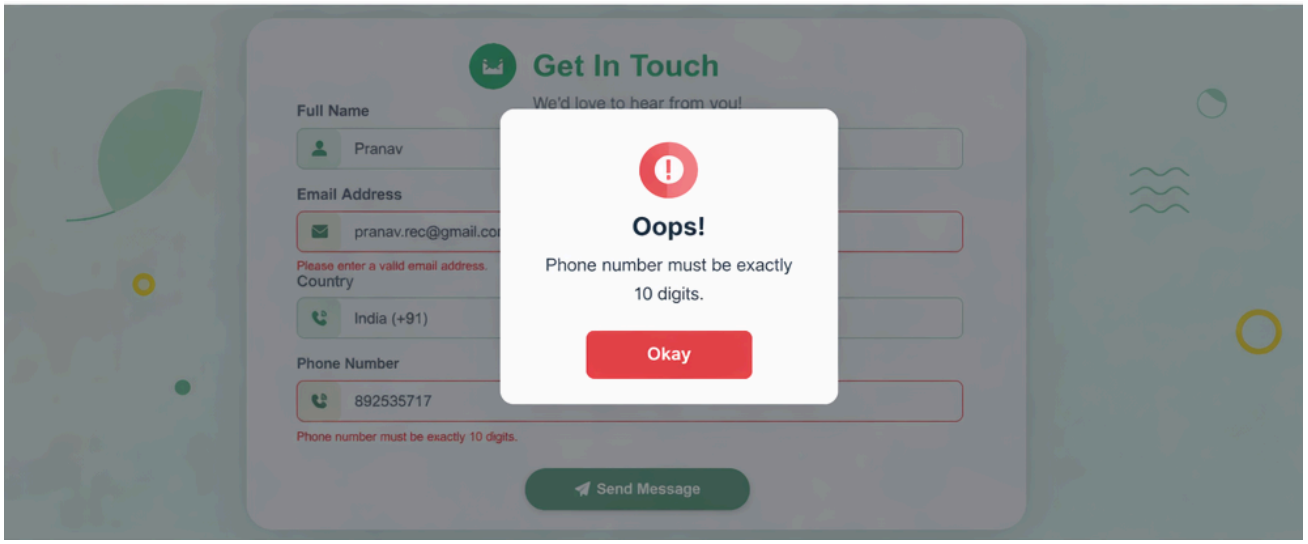
Finally, JavaScript is used to add validation to the form.

In this step, the input values are checked to make sure they are correct. For example, the email should be in proper format and the phone number should have the required number of digits.

A library like Validator.js can also be used to simplify the checking process.

If the user enters wrong data, error messages are shown on the screen. The form will not be submitted until all the values are correct.

This helps in making sure that only valid data is collected and reduces errors



CONCLUSION

This experiment helps to understand how form validation works using HTML, CSS, and JavaScript. It also shows the importance of checking user input to avoid errors and improve data accuracy.
